Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).

Description

The present invention relates to a corrosion inhibiting conductive coating which provides EMI/RFI shielding and prevents corrosion when applied to conductive substrates.

When dissimilar metal and/or conductive composite substrates are joined together in the presence of an electrolyte, a galvanic potential is established at the interface between the substrates. If this assembly is exposed to the environment, particularly under severe conditions such as salt fog or salt fog containing a high concentration of SO_2 , corrosion of the least noble of the substrates will occur, causing failure of the assembly. Mechanisms other than the establishment of galvanic potentials, e.g. crevice corrosion, may also cause corrosion and eventual failure of the part. In these cases one or all of the exposed materials in the assembly may corrode.

Thus, it has long been an object, especially among manufacturers of aircraft mainframes, ships, telecommunication equipment and other such equipment which is to be exposed to the environment, to prevent corrosion at these interfaces.

Further, it is often necessary to provide EMI/RFI shielding to the equipment described above, as aircraft, ships, etc, frequently utilize electronic systems which either radiate or are susceptible to electromagnetic or radio frequency interference (EMI/RFI).

Various methods have been attempted to achieve one or both of these objectives. Conventional shielding gaskets have been used in these applications to provide EMI/RFI shielding. These gaskets generally provide satisfactory shielding, but do not address the problem of corrosion. In fact, when the metal filler or mesh in the shielding gasket is different from either of the substrates a galvanic potential is established across all three elements, often causing the gasket itself, and eventually the entire assembly, to corrode.

Coatings comprising polymers and nickel filler have been applied to the substrates in an attempt to improve shielding and reduce corrosion. This approach is capable of providing acceptable shielding effectiveness of the assembly, but under conditions in which the coating remains conductive it has little or no effect on corrosion protection.

Some success in preventing corrosion has been obtained by sealing the interface with polythioether or polysulfide sealants containing chromate corrosion inhibitors. However, it is difficult to handle and to dilute these systems enough to use them as sprayable coatings, which are generally preferred for their ease of application. Further, they do not exhibit good thermal stability and become brittle over time.

EP-A-170 063 describes copper-containing coating compositions which comprise copper powder, a coating binder resin and an antioxidant selected from certain specific salicyloyl-substituted triazoles and alkyl or allyl trithiophosphites.

EP-A-300 453 describes similar compositions which comprise, as antioxidant certain salicylic acid derivatives. The compositions are stated to be an improvement on those of EP-A-170 063 in terms of initial conductivity and long-term stability.

Thus it is desired to provide a coating which will resist the corrosion of conductive substrates, even in severe environments, while maintaining good EMI/RFI shielding. It is further desired to provide such a coating without the use of hazardous chromates.

The present invention is directed to a corrosion inhibiting EMI/RFI shielding coating composition. More particularly, the invention is directed to a corrosion inhibiting conductive coating comprising a fluorinated polyurethane resin which comprises a first polymer selected from the group consisting of isocyanates and isocyanate terminated prepolymers, and a fluorinated second polymer selected from the group consisting of polymers having an amine functionality, polymers having a hydroxyl functionality, polymers having both amine and hydroxyl functionalities, and mixtures thereof; a stabilized conductive filler; and an azole selected from aromatic triazoles, imidazoles and thiazoles.

In one embodiment of the invention the corrosion inhibiting coating comprises a polyurethane resin comprising a first polymer selected from the group consisting of isocyanates and isocyanate terminated castor oil prepolymers, and a second polymer selected from the group consisting of polyether polyols, polythiols and polyamines; a stabilized copper powder; and a triazole selected from the group consisting of alkyl substituted aromatic triazoles and other triazoles.

In a preferred embodiment the coating comprises from about 10 to 50 weight percent fluorinated polyurethane, from about 30 to 80 weight percent stabilized conductive filler, and from about 0.1 to 3 weight percent aromatic triazole, based on the total solids in the coating composition. It is also preferred that the weight ratio of the first to second polymer be from about 1:2 to 1:6, and that the stabilized conductive filler be a stabilized copper powder.

In its method aspects, the present invention is directed to a method of coating conductive substrates to prevent corrosion when these substrates are exposed to harsh environments, e.g. in naval and aerospace applications, while maintaining good EMI/RFI shielding. This method comprises the steps of a) providing a corrosion inhibiting conductive coating comprising a polyurethane resin which comprises a first polymer selected from the group consisting of isocyanates and isocyanate terminated prepolymers, and a fluorinated second polymer selected from the group consisting of polymers having an amine functionality and polymers having a hydroxyl functionality; a stabilized conductive filler; and an aromatic triazole; and b) applying the corrosion inhibiting coating to a conductive substrate. The method may

further comprise the additional step of curing the coating. The coating may be cured for at least 15 minutes, and preferably 30 minutes at 121°C (250°F), or at least 5 days, and preferably 7 days at ambient temperature.

The present invention further provides a substrate coated with a coating according to the invention. The coated substrate may be bonded to a second substrate or a gasket to form an assembled part and exposed to severe environments such as salt fog with minimal corrosion of the part.

The present invention relates to a corrosion inhibiting coating comprising a fluorinated polyurethane resin, a stabilized conductive filler, and an aromatic triazole. It has been found that this combination unexpectedly provides excellent corrosion resistance to a variety of conductive substrates, even under severe conditions such as long term exposure to salt fog, salt fog containing a high concentration of SO₂, etc.

The coating of the invention is generally provided as a two component system, with the hydroxy or amine functional second polymer (part A), and the isocyanate terminated first polymer (part B) being stored separately until the time of use. Generally, the stabilized conductive filler, aromatic triazole, and any other optional ingredients are incorporated in part A. Part A and part B, when stored separately, are generally shelf stable for at least 6 months at ambient temperature. When the two components are mixed, the mixture will begin to increase in viscosity as it crosslinks until it eventually gels. The time during which the mixture is of a workable viscosity, i.e. the pot life of the coating, will vary depending upon the hydroxyl number of the second polymer, the batch size, the solids level of the composition, and any optional accelerators, diluents or inhibitors present in the coating composition. The pot life will generally be from about 15 minutes to about 1 hour. After the coating is applied to a substrate, chain extension and/or cross-linking will continue, but at slower rate since the coating is now present in a thin film and the exothermic cure reaction is unable to generate as much heat as when the mixture was present in a large mass. Thus the cure time of an unaccelerated coating composition in a thin film will generally be at least 5 days, and usually 7 days at ambient temperature. If a faster cure is desired the coating may be heat cured. In this case, it is preferred that the coating be cured for at least 15 minutes, and preferably 30 minutes at about 121°C (250°F). It is particularly preferred that the coating be allowed to dry for approximately 30 minutes at ambient temperature before heat curing. The rate of cure may also be accelerated by the addition of optional accelerators such as metallic catalysts, e.g. dibutyltin dilaurate, although the addition of an accelerator will also tend to shorten the pot life of the mixture.

Many combinations of hydroxy or amine functional and isocyanate-functional polymers may be successfully used in the present invention to form the reacted polyurethane. It is generally preferred that the polyurethane be hydrophobic.

It is also preferred that the second polymer be selected from the group consisting of polyether polyols and polyether amines. The preferred molecular weight and hydroxyl number of the second polymer will vary based on the requirements of the given application; the higher the hydroxyl number, the better the adhesion and chemical resistance of the coating, but the shorter its pot life. Additionally, the higher the molecular weight of the second polymer, the better the chemical resistance of the coating. For most applications, a molecular weight of from 2000 to 150,000 and hydroxyl number of from 25 to 100 are preferred. It is also generally preferred that the hydroxyl or amine functionality be greater than 1. Particularly preferred polymers are fluoroolefin vinyl ethers, such as those commercially available from I.C.I. Americas, Inc. under the tradename LUMIFLON®. These polymers generally have a molecular weight of from about 4000 to 150,000 and a fluorine content of from 25% to 30%. A particularly preferred polyether amine is polytetramethyleneoxide-di-p-aminobenzoate, commercially available from Polaroid Corp. under the tradename POLYAMINE® 1000. Polythiols which may be used in the invention include polyether/thioether polyols.

Most isocyanate resins and isocyanate terminated prepolymers may be used in the invention. Methylene diisocyanate and reaction products thereof with castor oil are generally preferred. Particularly preferred is a methylene diisocyanate terminated castor oil prepolymer which is commercially available from Aceto Chemical under the tradename URIC 2023. This polymer is preferred because the castor oil is a high purity grade and provides an excellent coating.

The term "stabilized conductive filler" as used herein refers to any electrically conductive filler which has been treated such that the surfaces of the filler particles are protected from oxidation and the filler remains electrically conductive after such treatment. These stabilized fillers, when used in the coating compositions of the invention, have been found to greatly increase the resistance of the coated substrates to corrosion, especially during long term exposure to salt fog or heat, while maintaining sufficient electrical conductivity to provide EMI/RFI shielding. Such stabilized fillers may be obtained by purchasing them in prestabilized form from a manufacturer of stabilized fillers, or by purchasing unstabilized conductive fillers and treating them to prevent surface oxidation of the particles. A preferred prestabilized filler for use in the invention is a stabilized copper powder, which is commercially available in prestabilized form from Fujikura Kasei of Japan under the tradename Fujikura® CP-10. This prestabilized filler is a silver plated copper powder produced by a substitution plating process. This process is described in detail in Japanese Patent No. 53/134759, and comprises coating copper powder with silver metal using a silver complex salt solution comprising from 3 to 30 weight percent silver nitrate, from 15 to 70 weight percent ammonium bicarbonate, and from 23 to 75 weight percent trisodium ethylenediaminetetraacetic acid. The ratio of silver to copper in the final product is generally from 5:95 to 50:50, and preferably from 10:90 to 30:70. Other prestabilized fillers may also be used in the invention. If it is desired by the user to stabilize the filler this may be accomplished by coating the surface of the filler particles with a material which will

inhibit oxidation of the particle, generally a noble metal such as gold or silver or a fatty acid. The filler may be coated by mixing or milling the filler with a silver salt and/or a fatty acid, preferably for a period of time adequate to coat substantially all of the filler particles. A method of treating fillers with fatty acids is disclosed in U.S. patent No. 4,781,980, the disclosure of which is incorporated herein by reference. Fillers which may be stabilized include, but are not limited to copper, nickel, silver plated metals, nickel-graphite fibers and combinations thereof.

Aromatic triazoles are known in the art as organic corrosion inhibitors, and are believed to directly bond to metal surfaces to produce inhibiting complexes. However, when used in conventional conductive coating systems they do not provide adequate corrosion protection in long term salt fog exposure. However, for reasons unknown to the inventor, in the coating of the invention, in combination with a polyurethane and a stabilized metal filler, the aromatic triazole provides excellent corrosion resistance during prolonged salt fog exposures of greater than 1000 hours on Al 3000 series alloys. In the coating of the invention, any azole may be used, preferably an aromatic triazole, an imidazole, or a thiazole, and most preferably an alkyl substituted aromatic triazole, e.g. tolyltriazole and benzotriazole. These chemicals are readily available commercially. A particularly preferred triazole is a proprietary material available from PMC Specialties Group under the tradename COBRATEC® 205. Generally triazoles are acidic, and thus at higher levels the triazole may alter the cure characteristics of the composition, slightly reducing the chemical resistance of the cured coating. For optimal cure characteristics, in applications where high chemical resistance is required, a neutral or alkaline azole, such as 2,5-(aminopentyl)-benzimidazole (commercially available from Mobay Chemical, under the tradename Preventol Trial Products C.T-3) may be used instead of the triazole component of the coating composition.

Additionally, the coating of the invention may further optionally comprise a chromate salt. This additional additive is preferred in applications where the coating is to be applied to a metal and exposed to mechanical abuse which may cause scratching of the coating. It has been found that the addition of chromates to the coating enables the cured coating to "self-heal" when it is scratched, thereby improving the integrity of the coating and the protection of the underlying metal surface. This property is generally not required when the coating is to be used on a non-metal (e.g. composite) substrate. A preferred chromate salt is zinc chromate, and it is generally preferred that the chromate be present in the composition at a level of from about 0.01 to about 15 weight percent based on the total solids in the coating composition. It is generally convenient to add the chromate to the composition by first milling it with a portion of the second polymer and then adding it to part A of the composition.

Optionally, the coating composition may further comprise such conventional additives as surfactants, accelerators, inhibitors, diluents and active solvents, in amounts which do not deleteriously effect the properties of the coating. In the case of solvents, different solvents may be used depending on whether the coating is to be sprayed, brushed, etc., e.g. if a higher solids coating is desired for brush application it may be advantageous to use a low vapor pressure solvent such as a di-methyl ester mixture, e.g. a mixture of dimethyl succinate, dimethyl glutarate and dimethyl adipate to extend the pot life of the composition. A particularly preferred dimethyl ester mixture comprises about 25% dimethyl succinate, about 55% dimethyl glutarate, and about 20% dimethyl adipate. The amount of solvent present in the composition will depend on the particular solvent used, and the desired viscosity of the coating. If a low v.o.c. (volatile organic compound) coating is desired, it is generally necessary to brush-apply the coating, so that a lower level of solvent may be used, e.g. the ratio of solids to solvent may be from about 50:50 to 40:60.

In a preferred embodiment of the invention the polyurethane resin is present in an amount of from about 10 to 50 weight percent of the composition, and the first and second polymers are present in a weight ratio of from about 1:2 to 1:6; the stabilized conductive filler is present in an amount of from about 30 to 80 weight percent of the composition; and the azole is present in an amount of from about 0.1 to 3 weight percent of the composition, based on the total solids in the coating composition. Particularly preferred levels are from 10 to 25 weight percent of the polyurethane, from 40 to 70 weight percent of the filler, and from 0.5 to 1.75 percent of the triazole. A weight ratio of 1:3.2 of the first to second polymer is particularly preferred. Unless otherwise specified, all weight percents given herein are based on the total weight of solids in the coating composition.

The present invention is further directed to a method of inhibiting corrosion of substrates while maintaining EMI/RFI shielding comprising the steps of a) providing a corrosion inhibiting conductive coating according to the invention and b) applying the corrosion inhibiting coating to a substrate. This method may further comprise the step of c) curing the coating. The coating may be cured as described hereinabove, either at room temperature or by heating the substrate. It is preferred that prior to heat curing the coating be allowed to dry for approximately 30 minutes at ambient temperature. The coating may be applied to the substrate by doctor blade, brushing, spraying, and other conventional coating techniques. Spraying is generally preferred for convenience.

The coating of the invention may be used on any solid substrate, e.g. metals such as aluminum or steel, and composites such as metal filled, glass or carbon filled, or other polymer composites.

The invention further provides a substrate which is covered with a coating of the invention. The substrate may be bonded to a second substrate or a gasket, forming an assembled part, and exposed to severe environments such as salt fog with minimal corrosion of the part. For purposes of EMI/RFI shielding, the substrates and gasket generally are electrically conductive.

The following examples are illustrative of preferred embodiments of the invention and not of limiting effect. Other variations and modifications of the invention may be practiced by those skilled in the art without departing from the spirit and scope of the invention.

5 Example 1

A corrosion inhibiting conductive coating of the invention was prepared using the formulation shown in Table 1. Part A was prepared by first mixing the xylene and the propylene glycol monomethyl ether acetate solvents, then dissolving the tolyltriazole in this solvent mixture, which mixture serves both as a solvent for the triazole powder and a
10 the triazole solution and mixed well. A conventional fluorocarbon surfactant (FC-430, commercially available from Minnesota Mining and Manufacturing) was then added and mixed. Then a 50% solution of a fluoroolefin vinyl ether polymer in xylene (LUMIFLON®601) was added, and the batch was again mixed.

2.8 parts of part B, which comprised a methylene diisocyanate terminated castor oil prepolymer (URIC 2023) were
15 then added to 97.2 parts of part A and mixed well. The resulting coating was spray coated on aluminum AL 35, (3000 alloy series), dried 15 minutes at ambient temperature, then cured for 30 minutes at 121°C (250°F), and tested, with results as shown in Table 2. The viscosity of the mixed coating composition doubled in approximately 45 minutes, which was considered to be the pot life of the mixture. The coated substrate was tack free, according to ASTM-D-1650, after 15 minutes at ambient temperature.

20 The data of Table 2 shows that the coating has excellent initial properties, and retains these properties for up to 1000 hours of salt fog exposure. Particularly importantly, a conductive interface having over 80 dB of EMI attenuation is maintained during the 1000 hour salt fog test. Additionally, no corrosion of the substrate was observed after the 1000 hour salt fog test.

EXAMPLE 2

A corrosion inhibiting coating according to another embodiment of the invention was prepared according to Example 1, except that the tolyltriazole was replaced with the same amount of a proprietary triazole available from PMC Specialties Group under the tradename COBRATEC® 205. The coating was tested as described in Example 1, with results as shown in Table 3.

The data of Table 3 shows that this coating also has excellent initial properties, and retains these properties during prolonged exposure to salt fog.

EXAMPLE 3

A corrosion inhibiting coating was prepared according to Example 2, with the further addition of 5 weight percent zinc chromate, based on the total solids of the coating.

This coating (Sample 1) was then applied to AL 2024-class III (aluminum 2000 series) and tested using the procedures described in Example 1, with each test being conducted on two specimens. One specimen was tested as coated, while the coating on the other specimen was scratched before initial testing and subsequent exposure to salt fog. The coating of Example 2 (Sample 2) was then tested both as coated and scratched, using identical procedures. The results of this testing are shown in Table 4.

Although the two formulations were not tested after the same number of hours exposure to salt fog, the data of Table 4 does demonstrate that after about 300 hours salt fog the scratched panels coated with the coating which contained zinc chromate retained much better surface conductivity and appearance than those coated with the coating of example 2.

While the present invention has been described with reference to its preferred embodiments, other embodiments, variations and modifications can achieve the same result. Variations, modifications and equivalents of the present invention will be obvious to those skilled in the art and it is intended to cover in the appended claims all such modifications and equivalents as fall within the true spirit and scope of this invention.

Claims

1. A corrosion inhibiting conductive coating comprising:

(a) a fluorinated polyurethane resin comprising:

- (i) a first polymer which is an isocyanate or isocyanate terminated prepolymer; and
- (ii) a fluorinated second polymer having an amine functionality, a hydroxyl functionality, both amine and hydroxyl functionality, or a mixture thereof;

(b) a stabilized conductive filler; and

(c) an azole selected from aromatic triazoles, imidazoles and thiazoles.

2. A corrosion inhibiting conductive coating comprising:

(a) from about 10 to 50 weight percent of a fluorinated polyurethane resin comprising:

- (i) a first polymer selected from the group consisting of isocyanates and isocyanate terminated prepolymers; and
- (ii) a fluorinated second polymer selected from the group consisting of amines, polythiols and polyether polyols;

(b) from 30 to 80 weight percent of a stabilized conductive filler; and
(c) from about 0.1 to 3 weight percent of an azole selected from the group consisting of aromatic triazoles, imidazoles or thiazoles.

- 5 3. A coating according to claim 1 or 2 wherein the polyurethane resin is from 10 to 25 weight percent of the coating.
4. A coating according to claim 1, 2 or 3 wherein the first and second polymers are present in a weight ratio of from about 1:2 to 1:6.
- 10 5. A coating according to any one of the preceding claims wherein the stabilized conductive filler is from about 40 to 70 weight percent of the coating.
6. A coating according to any one of the preceding claims wherein the aromatic triazole is from about 0.5 to 1.75 weight percent of the coating.
- 15 7. A coating according to any one of the preceding claims wherein the first polymer is an isocyanate.
8. A coating according to claim 7 wherein the isocyanate is methylene diisocyanate.
- 20 9. A coating according to any one of the preceding claims wherein the first polymer is a methylene diisocyanate terminated castor oil prepolymer.
10. A coating according to any one of the preceding claims wherein the second polymer is a fluoroolefin vinyl ether copolymer.
- 25 11. A coating according to any one of the preceding claims wherein the stabilized conductive filler is selected from the group consisting of stabilized copper powder, nickel powder, silver plated metals, nickel-graphite fibers and mixtures thereof.
- 30 12. A coating according to claim 11 wherein the stabilized copper powder is produced by a process which comprises coating copper powder with silver metal using a silver complex salt solution comprising from 3 to 30 weight percent silver nitrate, from 15 to 70 weight percent ammonium bicarbonate, and from 23 to 75 weight percent trisodium ethylenediaminetetraacetic acid.
- 35 13. A coating according to any one of the preceding claims wherein the stabilized conductive filler is produced by coating an unstabilized conductive filler with a fatty acid.
14. A coating according to any one of the preceding claims wherein the stabilized conductive filler is produced by coating an unstabilized conductive filler with a noble metal.
- 40 15. A coating according to any one of the preceding claims wherein the aromatic triazole is selected from the group consisting of tolytriazole and benzotriazole.
16. A coating according to any one of the preceding claims further comprising a chromate salt.
- 45 17. A coating according to claim 16 wherein the chromate salt is zinc chromate.
18. A corrosion inhibiting conductive coating according to any one of the preceding claims wherein the second polymer has a hydroxyl or amine functionality of greater than 1.
- 50 19. A method of inhibiting corrosion of conductive substrates while maintained EMI/RFI shielding which comprises applying to a conductive substrate a corrosion inhibiting coating according to any one of claims 1 to 18.
20. A method according to claim 19 further comprising the step of curing the corrosion inhibiting coating.
- 55 21. A method according to claim 19 or 20 wherein the coating is cured for at least 30 minutes at 121°C (250°F).
22. A method according to claim 19 or 20 wherein the coating is cured for at least 5 days at room temperature.

23. A method according to any one of claims 19 to 22 wherein the coating is applied to the conductive substrate by spraying.
24. A corrosion resistant substrate comprising a conductive substrate and, on the surface of said conductive substrate, a corrosion inhibiting coating according to any one of claims 1 to 18 or a coating applied by a method according to any one of claims 19 to 23.
25. A corrosion resistant substrate according to claim 24 wherein the conductive substrate is aluminium.
26. A corrosion resistant substrate according to claim 24 wherein the conductive substrate is a metal filled composite.

Patentansprüche

1. Korrosionshemmende leitende Beschichtung, die

(a) ein fluoriertes Polyurethanharz, das

- (i) ein erstes Polymer, das ein Isocyanat oder ein Präpolymer mit Isocyanat-Endgruppen ist; und
(ii) ein fluoriertes zweites Polymer mit Aminfunktionalität, Hydroxyfunktionalität, sowohl Amin- als auch Hydroxyfunktionalität oder eine Mischung dieser Polymere umfaßt;

(b) einen stabilisierten leitenden Füllstoff; und

(c) ein Azol ausgewählt aus aromatischen Triazolen, Imidazolen und Thiazolen umfaßt.

2. Korrosionshemmende leitende Beschichtung, die

(a) etwa 10 bis 50 Gew.% eines fluorierten Polyurethanharzes, das

- (i) ein erstes Polymer ausgewählt aus der Gruppe bestehend aus Isocyanaten und Präpolymeren mit Isocyanat-Endgruppen; und
(ii) ein fluoriertes zweites Polymer ausgewählt aus der Gruppe bestehend aus Aminen, Polythiolen und Polyetherpolyolen

umfaßt;

(b) 30 bis 80 Gew.% eines stabilisierten leitenden Füllstoffs; und

(c) etwa 0,1 bis 3 Gew.% eines Azols ausgewählt aus der Gruppe bestehend aus aromatischen Triazolen, Imidazolen und Thiazolen umfaßt.

3. Beschichtung nach Anspruch 1 oder 2, bei der das Polyurethanharz 10 bis 25 Gew.% der Beschichtung ausmacht.

4. Beschichtung nach Anspruch 1, 2 oder 3, bei der das erste und zweite Polymer in einem Gewichtsverhältnis von etwa 1:2 bis 1:6 vorhanden sind.

5. Beschichtung nach einem der vorhergehenden Ansprüche, bei der der stabilisierte leitende Füllstoff etwa 40 bis 70 Gew.% der Beschichtung ausmacht.

6. Beschichtung nach einem der vorhergehenden Ansprüche, bei der das aromatische Triazol etwa 0,5 bis 1,75 Gew.% der Beschichtung ausmacht.

7. Beschichtung nach einem der vorhergehenden Ansprüche, bei der das erste Polymer ein Isocyanat ist.

8. Beschichtung nach Anspruch 7, bei der das Isocyanat Methylendiisocyanat ist.

9. Beschichtung nach einem der vorhergehenden Ansprüche, bei der das erste Polymer ein Präpolymer mit Methylendiisocyanat-Endgruppen auf Basis von Rizinusöl ist.

10. Beschichtung nach einem der vorhergehenden Ansprüche, bei der das zweite Polymer ein Fluorolefin/Vinylether-

Copolymer ist.

11. Beschichtung nach einem der vorhergehenden Ansprüche, bei der der stabilisierte leitende Füllstoff ausgewählt ist aus der Gruppe bestehend aus stabilisiertem Kupferpulver, Nickelpulver, versilberten Metallen, Nickel-Graphit-Fasern und Mischungen derselben.
12. Beschichtung nach Anspruch 11, bei der das stabilisierte Kupferpulver nach einem Verfahren hergestellt ist, bei dem Kupferpulver unter Verwendung einer Silberkomplexsalzlösung, die 3 bis 30 Gew.% Silbernitrat, 15 bis 70 Gew.% Ammoniumbicarbonat und 23 bis 75 Gew.% Trinatriummethylen-diamintetraessigsäure umfaßt, mit Silbermetall beschichtet wird.
13. Beschichtung nach einem der vorhergehenden Ansprüche, bei der der stabilisierte leitende Füllstoff durch Beschichten eines nicht stabilisierten leitenden Füllstoffs mit einer Fettsäure hergestellt ist.
14. Beschichtung nach einem der vorhergehenden Ansprüche, bei der der stabilisierte leitende Füllstoff durch Beschichten eines nicht stabilisierten leitenden Füllstoffs mit einem Edelmetall hergestellt ist.
15. Beschichtung nach einem der vorhergehenden Ansprüche, bei der das aromatische Triazol ausgewählt ist aus der Gruppe bestehend aus Tolyltriazol und Benzotriazol.
16. Beschichtung nach einem der vorhergehenden Ansprüche, die außerdem ein Chromatsalz umfaßt.
17. Beschichtung nach Anspruch 16, bei der das Chromatsalz Zinkchromat ist.
18. Korrosionshemmende leitende Beschichtung nach einem der vorhergehenden Ansprüche, bei der das zweite Polymer eine Hydroxyl- oder Aminfunktionalität größer als 1 hat.
19. Verfahren zur Hemmung der Korrosion von leitenden Substraten unter Aufrechterhaltung der EMI/RFI-Abschirmung, bei dem auf ein leitendes Substrat eine korrosionshemmende Beschichtung gemäß einem der Ansprüche 1 bis 18 aufgebracht wird.
20. Verfahren nach Anspruch 19, bei dem außerdem die korrosionshemmende Beschichtung gehärtet wird.
21. Verfahren nach Anspruch 19 oder 20, bei dem die Beschichtung mindestens 30 Minuten bei 121°C (250°F) gehärtet wird.
22. Verfahren nach Anspruch 19 oder 20, bei dem die Beschichtung mindestens 5 Tage bei Raumtemperatur gehärtet wird.
23. Verfahren nach einem der Ansprüche 19 bis 22, bei dem die Beschichtung durch Sprühen auf das leitende Substrat aufgebracht wird.
24. Korrosionsbeständiges Substrat, das ein leitendes Substrat und auf der Oberfläche des leitenden Substrats eine korrosionshemmende Beschichtung gemäß einem der Ansprüche 1 bis 18 oder eine nach einem Verfahren gemäß einem der Ansprüche 19 bis 23 aufgetragene Beschichtung umfaßt.
25. Korrosionsbeständiges Substrat nach Anspruch 24, bei dem das leitende Substrat Aluminium ist.
26. Korrosionsbeständiges Substrat nach Anspruch 24, bei dem das leitende Substrat ein metallgefüllter Verbundwerkstoff ist.

Revendications

1. Revêtement conducteur inhibant la corrosion comprenant :
(a) une résine polyuréthane fluorée comprenant :

- (i) un premier polymère qui est un isocyanate ou un prépolymère terminé par un isocyanate ; et
- (ii) un second polymère fluoré ayant une fonctionnalité amine, une fonctionnalité hydroxyle, ou à la fois une fonctionnalité amine et hydroxyle, ou leur mélange ;

- 5 (b) une charge conductrice stabilisée ; et
- (c) un azole choisi parmi les triazoles aromatiques, les imidazoles et les thiazoles.

2. Revêtement conducteur inhibant la corrosion comprenant :

- 10 (a) d'environ 10 à 50 pour cent en poids d'une résine de polyuréthane fluorée comprenant :

- (i) un premier polymère choisi dans le groupe consistant des isocyanates et des prépolymères terminés par un isocyanate ; et
- 15 (ii) un second polymère fluoré choisi dans le groupe consistant des amines, des polythiols et des polyéther polyols;

- (b) de 30 à 80 pour cent en poids d'une charge conductrice stabilisée ; et
- (c) d'environ 0,1 à 3 pour cent en poids d'un azole choisi dans le groupe consistant des triazoles aromatique, des imidazoles ou des thiazoles.

- 20 3. Revêtement selon la revendication 1 ou 2, dans lequel la résine polyuréthane est de 10 à 25 pour cent en poids du revêtement.
- 25 4. Revêtement selon la revendication 1, 2 ou 3, dans lequel les premier et second polymères sont présents en un rapport en poids d'environ 1:2 à 1:6.
- 5. Revêtement selon l'une quelconque des revendications précédentes, dans lequel la charge conductrice stabilisée est d'environ 40 à 70 pour cent en poids du revêtement.
- 30 6. Revêtement selon l'une quelconque des revendications précédentes, dans lequel le triazole aromatique est d'environ 0,5 à 1,75 pour cent en poids du revêtement.
- 35 7. Revêtement selon l'une quelconque des revendications précédentes, dans lequel le premier polymère est de l'isocyanate.
- 8. Revêtement selon la revendication 7, dans lequel l'isocyanate est le méthylène diisocyanate.
- 9. Revêtement selon l'une quelconque des revendications précédentes, dans lequel le premier polymère est un prépolymère d'huile de ricin terminé par un méthylène diisocyanate.
- 40 10. Revêtement selon l'une quelconque des revendications précédentes, où le second polymère est un copolymère de fluorooléfine vinyl éther.
- 45 11. Revêtement selon l'une quelconque des revendications précédentes, dans lequel la charge conductrice stabilisée est choisie dans le groupe consistant d'une poudre de cuivre stabilisée, d'une poudre de nickel, de métaux plaqués d'argent, de fibres nickel-graphite et de leurs mélanges.
- 50 12. Revêtement selon la revendication 11, dans lequel la poudre de cuivre stabilisée est produite par un procédé qui comprend le revêtement d'une poudre de cuivre avec un métal argent en utilisant une solution de sel d'un complexe d'argent comprenant de 3 à 30 pour cent en poids de nitrate d'argent, de 15 à 70 pour cent en poids de bicarbonate d'ammonium, et de 23 à 75 pour cent en poids d'acide trisodium éthylènediaminetétraacétique.
- 55 13. Revêtement selon l'une quelconque des revendications précédentes, dans lequel la charge conductrice stabilisée est produite par revêtement d'une charge conductrice non stabilisée avec un acide gras.
- 14. Revêtement selon l'une quelconque des revendications précédentes, dans lequel la charge conductrice stabilisée est produite par revêtement d'une charge conductrice non stabilisée avec un métal noble.

EP 0 437 979 B1

15. Revêtement selon l'une quelconque des revendications précédentes, dans lequel le triazole aromatique est choisi dans le groupe consistant en tolytriazole et du benzotriazole.
- 5 16. Revêtement selon l'une quelconque des revendications précédentes, comprenant de plus un sel chromate.
17. Revêtement selon la revendication 16, dans lequel le sel chromate est du chromate de zinc.
18. Revêtement conducteur inhibant la corrosion selon l'une quelconque des revendications précédentes, dans lequel le second polymère a une fonctionnalité hydroxyle ou amine supérieure à 1.
- 10 19. Méthode d'inhibition de la corrosion de substrats conducteurs avec un blindage FMI/RFI maintenu qui comprend l'application à un substrat conducteur d'un revêtement inhibant la corrosion selon l'une quelconque des revendications 1 à 18.
- 15 20. Méthode selon la revendication 19, comprenant de plus l'étape de polymériser le revêtement inhibant la corrosion.
21. Méthode selon la revendication 19 ou 20, dans laquelle le revêtement est polymérisé pendant au moins 30 minutes à 121°C (250°F).
- 20 22. Méthode selon la revendication 19 ou 20, dans laquelle le revêtement est polymérisé pendant au moins 5 jours à température ambiante.
23. Méthode selon l'une quelconque des revendications 17 à 22, dans laquelle le revêtement est appliqué au substrat conducteur par vaporisation.
- 25 24. Substrat résistant à la corrosion comprenant un substrat conducteur et, sur la surface dudit substrat conducteur, un revêtement inhibant la corrosion selon l'une quelconque des revendications 1 à 18, ou un revêtement appliqué par une méthode selon l'une quelconque des revendications 19 à 23.
- 30 25. Substrat résistant à la corrosion selon la revendication 24, dans lequel le substrat conducteur est de l'aluminium.
26. Substrat résistant à la corrosion selon la revendication 24, dans lequel le substrat conducteur est un composite chargé de métaux.
